

Install Jekyll 2 on Ubuntu 14.04 (//michaelchelen.net/81fa/install-jekyll-2-ubuntu-14-04)

MAY 14, 2014

Jekyll 2 was recently released (<http://jekyllrb.com/news/2014/05/06/jekyll-turns-2-0-0/>) and can be installed on Ubuntu 14.04 using `apt-get` and `gem install`. Additional features such as Rdiscount can be added with the same method. Although there are packages for Jekyll in the [Ubuntu repository](http://packages.ubuntu.com/search?keywords=jekyll&searchon=names&suite=all§ion=all) (<http://packages.ubuntu.com/search?keywords=jekyll&searchon=names&suite=all§ion=all>), the packages are for older versions of Jekyll.

Jekyll is a static site generator with a templating system that can be adapted for many types of websites, including blogs. It can be run on a server, or run locally and the generated files uploaded to a server. It is the default software used by Github Pages.

Tested with Jekyll 2.1.1 and Ubuntu Server 14.04

Install Prerequisites

Install ruby, the ruby development libraries, and the make command.

```
sudo apt-get install ruby ruby-dev make
```

Install Jekyll

Install the Jekyll gem system wide. For speed, we are excluding the extended documentation. To include all documentation, omit the `--no-rdoc --no-ri` switches.

```
sudo gem install jekyll --no-rdoc --no-ri
```

ExecJS Workaround

There is a [current issue \(https://github.com/jekyll/jekyll/issues/2327\)](https://github.com/jekyll/jekyll/issues/2327) that causes Jekyll to require a JavaScript runtime even if it will not be used.

Install `nodejs` to work around this issue.

```
sudo apt-get install nodejs
```

Start Jekyll

Check that Jekyll has been successfully installed.

```
jekyll -v
```

The current version is `jekyll 2.1.1`.

Recommended

Although not required, `git` is often used to manage the files of a Jekyll website.

```
sudo apt-get install git
```

Additional gems can add features to Jekyll, such as the alternate `rdiscount` Markdown renderer.

```
sudo gem install rdiscount --no-rdoc --no-ri
```

Get Website Content

Now that Jekyll is installed, we need content for it to serve. We can either use a current website, or set up a new site from scratch.

Use Existing Site

Use `git` to clone an existing Jekyll website, such as this one!

```
git clone https://github.com/mchelen/michaelchelen.net.git
cd michaelchelen.net
```

Create New Site

The `new` command creates a directory structure and config files for a new Jekyll site.

```
jekyll new my-awesome-site
cd my-awesome-site
```

Start Jekyll

Now that the basic config and layout are available, start Jekyll to generate the website HTML and start a local server.

```
jekyll serve
```

Then visit <http://localhost:4000> (<http://localhost:4000>) in a web browser.

Jekyll is now successfully running!

Extra Options

Jekyll can watch the directory for changes and regenerate the website when files are modified.

```
jekyll serve -w
```

The default port `4000` can be changed, for example when running multiple Jekyll instances.

```
jekyll serve --port 4001
```

 Then visit `<http://localhost:4001>` in a web browser.

The website can be generated without starting a local server. The files are placed into the `_site` directory and can be uploaded to a web server.

```
jekyll build
```

Mike Chelen Mod Michael Zimmermann • a month ago

It sounds like you installed Jekyll through the package manager. Uninstall it with "sudo apt-get remove jekyll" then install it using the steps from this guide.

Fredrik • 2 months ago

I had some issues installing Jekyll, they resolved themselves after installing the ruby-dev package, though. Thanks!
